Meeting project deadlines: An Enterprise Architecture Point of View (PoV)

**Clear scope and
priorities**

Realistic planning

Consistent Tracking
(review progress frequently)

**Proactive
Communication**

**Adaptability &
Accountability**

KPIs influence the cost decision

A strategic roadmap to a unified, governed data foundation supporting regulatory compliance, customer insight, and sustainable growth

TCO = Acquisition Costs + Operating Costs + Maintenance Costs + Disposal Costs

Cloud Migration Strategies

A strategic roadmap to a unified, governed data foundation supporting regulatory compliance, customer insight, and sustainable growth

TCO = Acquisition Costs + Operating Costs + Maintenance Costs + Disposal Costs

**Rehosting

- Lift-and-shift
- Typically, An early cloud strategy deployed by the majority
- Can be automated with tools
- Easier to further optimize/re-architect one already in cloud
- Reduction in cost for server maintenance
- Minimal impact on staff

** Re-platforming

- Lift-Tinker-and-Shift
- Rehosting and Refactoring consideration
- Small cloud optimization changes
- More knowledge needed about the applications
- More cloud compatible not necessarily cloud native
- More skills are required

** Refactoring/ Rearchitecting

- Re-imagine the application
- Application modernization
- Typically leveraging initial 'lift-and-shift' strategy to exploit cloud-native features
- Long term business motivation
- One or more complex options
- Usually, the most expensive but at times the most beneficial

Repurchasing /Replace

- Moving to a different product

Retire

- Get rid of it

Retain

- Keep it (or usually do nothing for now)

** - Big three

Cloud Migration : Stages at a high level

Cloud Migration : Planning Visualization

Cloud vs on Premise

A strategic roadmap

Category	On-premise	Cloud	Risk
Upfront	Servers, storage, network, racks	Migration, re-architecture, training	On-prem: capacity mis-sized up front, with no easy way to return hardware. Cloud: migration overruns and app rework taking longer than planned.
Recurring infrastructure	Maintenance/support contracts (~10-15% of hardware per year)	Compute, storage, egress, support plan	On-prem: support costs rise as hardware ages, and vendors end-of-life gear. Cloud: price changes and usage-driven bills that are hard to forecast.
Facilities	Power, cooling, space, physical security	Included in rates	On-prem: energy price swings, space limits, physical incidents. Cloud: the provider's costs are passed through in pricing over time.
Software	Hypervisor, OS, backup, monitoring licenses	Often bundled, but third-party tools still apply	On-prem: vendor licensing changes (virtualization licensing is a recent example). Cloud: license mobility rules and paying twice for BYOL tools.
People	Sysadmins, network, storage, DC ops	Cloud engineers, FinOps, security	On-prem: key-person dependency and hiring difficulty. Cloud: skills gap, since cloud talent is expensive and misconfigurations are costly.

Cloud vs on Premise continued..

A strategic roadmap to a unified, governed data foundation supporting regulatory compliance, customer insight, and sustainable growth

Category	On-premise	Cloud	Risk
Resilience	Second site, DR hardware	Multi-region/AZ, backup storage	On-prem: DR rarely tested and often underfunded. Cloud: regional outages and concentration risk if you rely on one provider.
Hidden costs	Hardware refresh, overprovisioning, downtime	Idle resources, egress surprises, reserved-instance commitments	On-prem: stranded capital if demand shrinks. Cloud: commitment lock-in and vendor lock-in that makes leaving expensive.

A Data-Driven Approach to Cloud Migration Decisions

I selected some numbers that looked plausible for a mid-sized environment (about 400 vCPU, 2 TB RAM, 100 TB storage) and I made sure each column added up. Here's the rough logic behind each one:

On-prem hardware (\$480K): a ballpark for roughly 10-15 servers, a storage array, and networking at typical enterprise prices.

On-prem support (\$360K): about 15% of hardware cost per year over 5 years, the top of the usual 10-15% range.

Staffing (\$1.1M vs \$750K): about 1.5 FTE vs 1 FTE at roughly \$150K fully loaded per year. The FTE split is my assumption, not a benchmark.

Power, cooling, and space (\$250K): about \$50K a year, a rough estimate for that amount of equipment.

DR (\$250K), software (\$200K), migration (\$150K): judgment-based estimates with no calculation behind them.

Cloud compute (\$1.5M): the least grounded. For a steady 400 vCPU at typical committed pricing, a bottom-up calculation would likely come out well below this, so I probably overstated it. That would tilt the real comparison toward cloud.

Cloud storage and egress (\$240K, \$120K): rough guesses based on typical per-GB rates and moderate data transfer.

How TOGAF can be used for cloud migration?

TOGAF becomes really important framework during cloud migration.

BPMN (flowable) diagram – BNPL/Flex-pay screening

Dashed line = message flow between pools. Unlabeled gateway exit = yes.

Vertical Slice diagram – BNPL/Flex-pay screening

Solid = call in the slice. Dashed = external message or reuse. Dotted = data owner.

Vertical Slice diagram – BNPL/Flex-pay screening with Mesh

Dashed outline = pod (service + sidecar). Dashed link between sidecars = mTLS fabric.
Solid = call in the slice. Dotted = data owner. Mesh layer is proposed, not in the original build.

I added the mesh as a proposed layer between the API and the services.

The mesh has three parts:

Sidecar proxies: one attached to each service inside its pod (the dashed outline). This is the data plane, and it's the sidecar pattern you already know.

Dashed links between sidecars: the mTLS (mutual Transport Layer Security) traffic between services.

Control plane and observability: the control plane pushes policy to the proxies, and the proxies send back metrics and traces.
